

Docker image --> packed blueprint that contains dependencies, code everything that is needed to run the application.

Docker container --> virtual machine(VM) of light weight(less configuration).

Types of docker image:

1. Custom images --> create images based on the application.
2. Inbuilt images --> are available or ready-made --> docker hub.

`docker build -t <imagename>:<version> .` --> creating custom image.

`Docker run -it --name <contname> -p h.p:c.p <imagename>:<version>`

`-it` --> interactive terminal

`-td` --> detached terminal

Host port number(h.p) --> portnumber for exposing application.

Container port number (c.p) --> application port number.

Container life cycle:

1. `Docker ps` --> shows the running containers.
2. `Docker ps -a` --> shows running, stopped containers.
3. `Docker images` --> shows the list of images in docker.
4. `Docker start <container ID>` --> starts that container.
5. `Docker stop <container ID>` --> stops that container.
6. `Docker rm` --> delete container.
7. `Docker rmi` --> delete the image.
8. `docker logs <container ID>` --> checks the logs of containers.
9. `Docker inspect <containerID>` --> details of container.
10. `Docker restart <container ID>` --> restarts the container.
